

cally for your render, as you can then save the textures for your model in that very folder.

Before we apply any texture to the model, you must first unwrap it.

Unwrapping: This is a process in which the mesh is cut at some edges (called seams) and laid out flat so that a texture can be applied onto it.

To unwrap your model, you need to define some edges as seams for it to cut and open on those edges. But these edges are prone to discontinuity in the texture. So these seams should be made only at places which will be hidden from the view of the camera. To achieve this, select the apple body

Unwrapping your model

and go to Edit Mode. Now select the edges you want to make a seam. You can select an edge loop by holding 'Alt' while selecting an edge or selecting all the individual edges of the loop. Press 'Ctrl+E' and from the menu, select Mark Seam. This will create a seam on the selected edges. Now imagine unfolding the geometry of your mesh. Add seams to edges wherever you feel the absolute need to. Finally, when you've marked the seams, in Edit Mode, select all the vertices and hit 'U' on the keyboard and select Unwrap. To see the unwrapped mesh, split the window into two and bring up UV/Image Editor on one window.

UV/Image Editor: This window is used to edit and paint on images or edit unwrapped UVs.

Now, in the viewport, select all the vertices of the mesh in Edit Mode, and you should see the unwrapped mesh in the UV/Image Editor window.
