

the middle of the arm, you might want to move it in the x-axis to align well with the backbone. Resize it, and we have this bone ready. Past this, we need to make three more bones, upper arm, arm and hand. The upper arm should ideally end at the elbow, the “arm” at the wrist, and the hand at the point the fingers begin, or somewhere halfway to that point in the palm. To be precise about it, you can press `e+x` to extrude the bones only in the x-axis. Once this is ready for the right hand, we have a basic bone structure

Creating the bone structure for the arms.

for half of the humanoid ready, and we can move on to the other half. But before we do so, check the location of the shoulder bone on the x-axis since we'll be needing it for the other half.

**Step 8:** For the other side of the upper body, instead of doing everything from above from scratch we can duplicate, rotate and rescale the right side. To do so, zoom out and select all the bones starting with the hand and back to the shoulder. Press `shift + d` to make a duplicate that gets automatically gets attached to your mouse so it could be moved around. Now to use this duplicate we need them to face the other way. An intuitive and convenient way of doing this is to press `s` (for scale) and then `x` followed by `-1`. This would flip the duplicate structure around. Once this is done, we can place this as symmetrically as possible to the left.

For the duplicate structure, we can make use of the “flip names” option in the armature tab to keep it by our nomenclature system till now. Now the final thing to do to get our upper structure ready is to parent the arms
