

Like the arms, rig one leg first. The bone is offset to work like a real hip.

“with an offset” to the chest. To do so, simultaneously select the shoulder and the chest, press `ctrl+p` and choose “offset”. You would see a black dotted line connecting the shoulders to the chest bone. This is done to ensure that when the rigging is complete, and the model has animated the shoulders, arms and chest move simultaneously as a unit.

Step 9: Next we move on to the legs. We follow the same set of procedures that we did for the upper half in the lower half too. We first make an accurate assumption of the joint placement, mostly known as “eyeballing the joint” and add a bone. We again make the necessary changes to let the bone fit in. Once the upper leg is done, we can move on to the foot. In my model, as you can see, there are no feet per se. But we would still need the bones here for the rig to work perfectly. So we repeat what we did before and finish off with the right leg. We again follow the same procedure of duplicating, rotating and scaling to get done with left leg too. Now we offset our legs to the hip so that the rig can work perfectly.

Once we’re done with this, we have a basic skeletal system for a humanoid rig ready. All we have to do now is parenting our model to the armature.

Step 10: Now that the basic rig is done we’ve to attach it with the mesh. For this, go back to the object model and select the model you want to parent to the rig (basically, the base model). Then select the rig and press `ctrl+p`.
