

Method 1: By using the hotkey 'I': Location

It stands for Insert Keyframe.

It opens or brings up a list of attributes which can be keyframed.

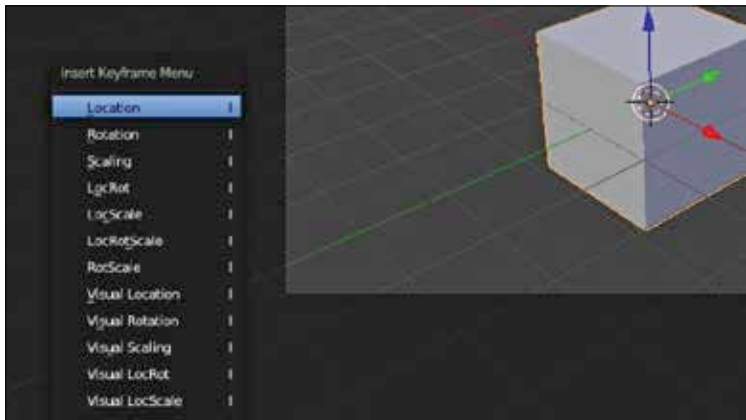

Location Keyframe: A location keyframe stores only the location data of an animation.

Rotation Keyframe: A rotation keyframe stores only the rotation data of animation of a 3-D object.

Scaling Keyframe: A scaling keyframe stores only the scale of the object.

LocRotScale Keyframe: Location, Rotation and Scaling can all be stored by the LocRotScale Keyframe to bring about multiple dimension changes together. However, it is recommended that the user only stores the required transformations at a time.

Let us try to animate a standard cube by inserting a location keyframe.

Source: Blender 3-D Animation Basics

Inserting a location keyframe

We first insert a location keyframe. Then we move to frame 200. (or 100, it is up to our choice). This can be done by typing 200 into the frame counter located just to the left of the playback buttons. This can also be done by scrubbing right along the timeline. The Keyframe can be seen represented by a yellow tick mark on the first frame (Frame 1).

This method essentially signals to Blender or tells the software where to place the cube on frame 1.

Now the cube is moved to the right on the 200th (or 100th) frame. When we reach the desired location, another location keyframe is inserted.
