

Navigating across the keyframes

Now we are ready for our animation. If we play using the play button or scrub through the timeline, we can observe that the cube starts to move.

For playing the animation at normal speed: The single arrow play button will play through the animation at normal speed. For jumping between keyframes: the double arrows button is used to jump between required keyframes. For jumping to the beginning or end of animation: the double arrows hitting the wall are used to execute this process.

Editing keyframes individually

Method 2: By using the hotkey 'I': Rotation

In this process, we are going to add rotation to the existing location animated object (cube). This can be done by using the keying sets. As we did earlier, we can specify the type of data we choose to be stored in the keying set dropdown. This time instead of the location we are now going to choose the rotation attribute from the menu.

Now we can either Press the hotkey 'I' to add a rotation keyframe in Blender. Or we can press the key button located directly to the right. These processes in Blender adds a new rotation keyframe. We can even choose to remove a keyframe. This can be done by using the slashed-key button to the right or by pressing the hotkey "ALT+I".

Now, as we did earlier, we go to the 200th frame (or 100th frame whichever we prefer). We rotate the cube a bit as per need and convenience. After we are finished, we press "I" again. This adds a rotation dimension. A point to be noted is that since the keying set is set to the only rotation, Blender software is instructed only to insert a rotation keyframe and not other kinds.
