

We know that transform properties are local. So now we increase the Z-value to the scaling level required (let us say 5 or 6) on frame 200 (or 100 as per what we chose earlier). Then we insert another single keyframe.

The scale thus gets magnified as expected in a single direction (unidirectional) which leads to the scaling method of magnification.

Beyond scaling, we can also choose to change the shape of an object over time. This involves more advanced and nuanced techniques.

Method 5: By using Automatic Keying

This method can be used to override all the current and preset settings of animation. Sometimes if used, it can accidentally erase all the data we have built till now, and thus must be used very carefully. However, this method

Use Automatic Keying carefully

can be beneficial when we want to block out poses quickly. This is because any changes we make are automatically inserted.

Auto-keying can be activated directly by toggling the red record button which is located to the left of the keying sets. The second key toggle that appears when auto keying is turned on allows us to only auto-key changes which are part of the active keying set. This active keying set included location, rotation, scaling among others.

Now to start the method, we first turn on auto-keying. With auto-keying turned on, we go to a particular frame number (say frame 100 or frame 50).
