

Keying Sets

On reaching the frame, we drag the cube upwards. This sends a signal to the software, and Blender automatically adds a new location keyframe for us. However, to prevent overwriting accidents, we need to turn auto-keying off after we are done; else it could lead to changes and loss of data leading to absurd animation settings and incomplete working of the desired project.

There are various other methods of animation apart from using keyframes, though using keyframes is the most widely used and sought-after form of animation in Blender due to its simplicity and diverse applications. One can also use simulation methods which are more advanced like Physics simulations to modify more complex objects than cubes. For example, human figures can also be animated and set in sequences of motion. The wider scope of animation can be seen from the following images.
