

What is a model?

Deep learning's basic building blocks

The basic building block of Keras is the model. The thing that enables you to summarize, fit, evaluate, and use to make prediction is a model. It is a way to organise layers. The sequence of tasks to be carried out while using Keras models are Model definition, Compilation of the model, Model fitting and finally performing predictions.

Deep learning models are highly repurposable by nature. We can reuse an image classification or speech to text model trained on a large scale dataset on a significantly different problem with only minor changes. Some of the well-known models, that you will come across while using neural networks, are simple multilayer perceptron, convolutional neural network, and recurrent neural network.
