

Getting started

All you need to know before jumping into into the code and structure.

First and foremost, have the latest version of Python with the packages – SciPy, NumPy, Matplotlib and Theano installed. You can choose to run these using the Jupyter notebooks through Anaconda or by using the terminal window but Anaconda is preferred.

Then install the Keras functionality to the program using the pip install function. You can confirm you have it installed by typing `$ pip` in your command line. This will produce a list of commands and options that come along with the package.

- `$ pip install keras $ python -c "import keras; print keras. version" $ pip install --upgrade keras`

Import the necessary libraries modules for keras including the sequential and python plots.

- from keras.models import Sequential, Keras core layer-
