

WORKING ON WORKBENCHES

Smaller datasets can be used in conjunction with simpler frameworks like Excel and Notepad++. Larger datasets require extensions that are proficient with Extraction/Transformation/Load (ETL).

These platforms help in storing multiple projections or formats of the same dataset so that different stakeholders can access them at different points. This is another central component to the data profiling step that we discussed earlier where the data has to be examined properly before it is worked on. Junk data should be identified early on and removed using the appropriate number of steps. Profiling is the best means of converting anything unnecessary to an arbitrary sequence.

It's necessary to have some of the project time compartmentalized on profiling the dataset columns and seeing which of them fall under particular types. Essentially all data column values can be of string, numeric or Boolean type. Boolean values require special consideration because of their binary nature. They are often the first to be encoded or split into separate columns.

When working on datasets in the workbench, have it inserted into the tabular format window and convert it into a pivot table. Pivoting is a great
