

Different Training methods

with a large amount of unlabeled data. Semi-supervised learning falls between unsupervised learning and supervised learning. These are used when you do not have enough labeled data to produce an accurate model

or you lack the resources to obtain more. Semi-supervised techniques can be used to increase the size of the training data. The snowball effect discussed earlier is employed here.

Semi-supervised Model

Validation

The stability of a machine learning model always needs to be validated. Validation techniques are used to estimate the error rate of the Machine Learning model. Generally, an error estimation for the model is calculated after training. In this process, the difference in predicted and original values are used to evaluate error, also called the training error.
