

Testing Dataset

While there are many ways to split up the original dataset into training and testing datasets, there are some basic principles that you can always follow, irrespective of the method. Most of the problems typically arise with the testing set. The testing dataset has to be large enough to provide statistically meaningful results. The testing set also has to be representative of the entire set, and cannot have drastically different characteristics. If the results are aligning to a surprisingly high degree, it is possible that portions of the testing set has leaked into the training set. **d**
