

- to get all the images in the train data zip file. It also retrieves all images with a dog in their name. We repeat the same procedure for cat images too.
2. Similarly, we get the test dataset also.
 3. Although the train data set contains 25,000 images, but since we only have access to little computational power, we're going to extract only 2000 images from both the dog and cat classes. This makes a training data set of 4000 images since we use the first 2000 images from the train_dogs and train_cats dataset respectively and then concatenate them into one train set called train_imgs. This will be our training dataset.
 4. Make sure that you randomly shuffle the train_imgs using the random function. This is required to remove the biases in the training data for the effective functioning of our model.
 5. Now the train_dogs and train_cats variables are useless, and they are taking unnecessary memory. Therefore, we delete them to prevent being run out of memory when we start training our model.

Viewing the images:

Now let us view our training set images to make sense of the work that we have been doing until now.

1. Import the image-plotting module from matplotlib that is the python library for plotting graphs and viewing images.
2. Now, run a loop to plot the number of images that you want to view from the train_imgs dataset.

Figure: Viewing images from the data set

Pre Processing the Images:

Pre-processing the images is a vital step for further execution of the model because deep learning models are very specific about the dimensions of the data that is input to them. We are going to resize the images using
