

Some Pre-trained Models:

There are different variants of pre-trained neural networks. Each has its architecture, size, speed, and share of advantages and disadvantages.

Keras comes pre-packaged with many types of these pre-trained models like:

1. VGGNET: Introduced by Simonyan and Zisserman in their 2014 paper, Very Deep Convolutional Networks for Large Scale Image Recognition. It was used in the previous model and gave an accuracy of around 80%.
2. RESNET: It was first introduced by He et al. in their 2015 paper - Deep Residual Learning for Image Recognition. It is a deep neural network that works on the core idea of so-called “identity shortcut connection” that skips one or more layers. Because of its compelling results, ResNet quickly became one of the most popular architectures in various computer vision tasks. It has boosted the ability to perform image classification, such as object detection and face recognition.
3. INCEPTION: The “Inception” micro-architecture was first introduced by Szegedy et al. in their 2014 paper - Going Deeper with Convolutions. It is a convolutional neural network (CNN) which is 27 layers deep but has some interesting layers called the inception layers that is the core concept of a sparsely connected architecture.

The inception layer is a combination of various layers such as 1×1 Convolutional layer, 3×3 Convolutional layer and 5×5 Convolutional layer with their output filter concatenated into a single output vector forming the input of the next stage.

The idea of an Inception module
