

- **Processor:** This provides you with the option of allocating the number of processors to the VM. Similarly, you can also fiddle with the number of cores.
- **Hard Disk:** A solid-state drive is always preferred over an HDD. Try to allocate your VM a sufficient amount of space so that you don't have to deal with partitioning and to swap shortly.
- **Network adapter:** To change the configuration of network adapters or add a virtual one. Generally, these three options are available under this option: Bridged, NAT, Host-only.

For our pen-test setup which communicates within the VM network, we'll go with the "Host-only" option.

4. To start the VM, click on the "OK" button followed by the "Play" button.
5. This will launch the virtual machine, and a boot screen will be displayed on the screen. Press Enter and when prompted for credentials enter "root" and "toor" as the username and password respectively. Now, we have complete access over the Kali Linux VM, and our VM can now be used for further hacking.
