

Rainbow Table

erate various combinations of lower and upper-case alphabets, numbers and symbols and try them to obtain the desired password. For example, if the password contains five characters, then it generates various combinations of 5 characters and attacks to get the password.

### Rainbow table attack

In this method, the hacker tries to use a rainboww hash table to crack the passwords stored in the database system. Whenever a user enters a password, it is converted to a hash value and is compared with the already stored hash value. If the values match, the user is granted access. A rainbow table contains hashes of commonly used hashes. The password hash is compared to the hashes present in the table to obtain the desired password.

### 3. Guessing

Sometimes the user forgets to change the defaults passwords like “password”, “admin” etc. which can be obtained by guessing. Common usage is also using things like date of birth, or company name, etc. Basically, any password that can be guessed by someone who knows a little about you is pretty useless.

### 4. Spidering

Another way to get access to your password is by gathering data using as many sources as possible just as a search engine would. Instead of a web search spider, you become the spider and search for information about the user. You can scour the company web site, social media accounts, etc. of the target and gather information. It's pretty silly to use your date of birth as a password if you also happen to post the same information on social media for all to see...
