

- eth - ethernet
- wlan - wireless lan

Type `ifconfig` on a terminal to view all the adapters. We need to check which of the wlan(0/1/2) adapter is active.

- Enable Monitor mode

Using a tool called `airmon-ng`, we create a virtual interface called `mon`.

```
airmon-ng start wlan0
```

The interface will be either named `mon0` or `wlan0mon` based on your Kali Linux version.

- Start capturing packets and store it in a file

Using `airodump-ng`, we capture the packets getting transferred by the Wi-Fi network. The name of the Wi-Fi you want to hack will be visible on the screen. By passing more parameters to it, you can store the data packets captured.
