

BeEF framework on Kali Linux

Working with BeEF:

1. Start up BeEF:

BeEF is developed into the Kali Linux operating system. It can be started as a system service and can be accessed using a web browser on your computer. You can start BeEF by going to Applications > Kali Linux > System Services > BeEF > `beef start`

2. Running a Web browser to BeEF

The BeEF server can be run from any browser on the localhost (127.0.0.1) web server at port 3000. Its authentication page can be accessed at <http://localhost:3000/ui/authentication>

For both username and password, “beef” is the default credential. Now log in to BeEF. BeEF displays its “Getting Started” window on the right side of the browser.

3. View the web browser details:

Clicking on the local browser will provide many choices, like a “Details” window where all the details of the used browser are displayed.

For example, it shows the version number of the browser, the platform on which it is used such as Linux i686, components like a flash, web sockets, and more Information that is useful for web application hacks.

4. Hooking a Web Browser

The main purpose of BeEF is to “hook” a browser, which essentially means to make the victim visit a vulnerable web app that is hooked up using BeEF.
