

data by providing a hybrid of an API pull and an algorithm to sort data that is extracted.

Hence, to retrieve data, first, we use Maltego transforms to split down a bigger and complex question into relatively smaller and simpler pieces. For instance, in the case of spoofing emails, first, we need to find out the email addresses associated with the organization that we are targeting. The second step is to expand the sample of email addresses that we have retrieved to include more samples. After our sample email size is adequate, we use a special Maltego transform to search for databases of breached accounts to find out if any of the emails in our sample have been previously involved in a breach. The final step is to enrich the breach data to learn about the details that were lost and the timeline of the data breach.

Spoofing emails using Maltego

The following steps give a detailed systematic procedure for spoofing emails. The same procedure can be applied to data mining.

Step 1. Install Maltego

To install Maltego, we need to install Java first. On the Kali Linux Operating System, Maltego is installed by default on the virtual machine. In case of macOS or Windows, Maltego can be installed from the Maltego Community Edition from the Paterva website.

Installing Maltego
