

Now our data is clean, and we have got rid of all the unwanted Information. Select all the email addresses in the Detail View pane to run a series of transforms on them. This will enable us to identify any accounts that may have been breached in the past. Right click on all the email addresses that have been selected and type “havebeenpwned” into the search bar to display all transform from the “Have I Been Pwned” transform set. These set of transforms will enable us to discover all breaches and Pastebin dumps that includes the email addresses that have been selected.

The transform will give a list of Pastebin dumps and account breaches, which are attributed to the selected email address. Now look for Pastebin URLs, which includes many lists of company email addresses. To expand the dataset, include email addresses found by other email scrapers like TheHarvester. We then run the transform as mentioned above on them to find whether they appear in any other Pastebin dumps.

Repeating this process several times will add many more email addresses to our list. On pasting a new email address, Maltego detects the data type automatically and assigns it too.

Step 6: Identifying the Email Addresses of Breached Employees

After gathering a list of emails of employees from our target organization, we now pass them through the “Have I Been Pwned” transform to examine the ones that may have been involved in a breach in the past. Select all of the email addresses, and click on the double “play” icon that is right next to the “havebeenpwned” transform item. This will run all the transforms contained in the “havebeenpwned” transform set simultaneously, and this looks for both the breaches and Pastebin dumps.

Results of Breached Employees
