

Soon after the transform has been processed on the data, we get a list of email addresses that were involved in breaches that were known in the past. Now since we have found out who was involved in the breaches and whose content was lost, our new aim is to find out who lost what.

Step 7: Discovering Lost Data in Email Breaches

To find out more Information on the breaches that the target employees were a victim too, we can select the breaches that we have discovered using the above transforms, and then enrich them. For enriching them, rich click the selected emails and type “enrich” in the search bar for showing the breach enrichment options. To learn details about the breach that occurred in the past and details about the type of data that was lost in that particular breach, run the above transform.

Now the profile of Information about each breach will be expanded to include the specific date of the breach. In addition to this, it will now also include an element to indicate the types of data that was lost – whether it was passwords, usernames, or other types of data.

Since, in this case, we want to spoof emails and find about the users who had lost their passwords, we will filter our results only to show those emails that have lost their passwords. To filter the Information, select all the “Password” entities in the pane on the right. Select “Add Parents” to add all of the elements that are connected as parent nodes to the elements whose passwords have been lost. Here, the parent node is the breached entity, and the “Passwords” element is the child node. Now, our results are filtered to include only those breaches where passwords were lost.

Clicking “Add Parents” once again, will add all of those email addresses, which are connected to these breaches that have lost passwords. Henceforth, we now have a list of email addresses those who have lost passwords in breaches. We also have the specific Information of when and how that Information of passwords was breached. In short, we have a targeted list of all the employees whose passwords were breached.

Step 8: Discovering Actual Passwords from Breached Datasets

Although discovering a breached password is relatively rare, but sometimes the Pastebin dump connected with the email address may be available as plain text. Pastebin dumps related to an email may contain much more Information than just the email address for instance – passwords in plain text.
