

practically every technology company on the surface of the planet have their own inhouse teams consisting of “ethical hackers”.

In this constantly evolving ecosystem, the lifetime of a vulnerability is severely limited. If security updates were forced down your throats, then you'd never have to worry because you'd have someone or the other looking over for you. Since you don't live in a fantasy land, you'll still find hundreds of folks with vulnerable systems who're completely in the dark about the same. Take for example Google Dorking, which relies on using Google search to identify system vulnerabilities. We used some of the techniques and spotted countless websites that were ripe for the taking. Now you see why kids often end up in jail for being “hackers”. They're simply running such simple techniques and it's shameful to be vulnerable to such known hacks.

This isn't the first FastTrack that we've come out with around the topic of Ethical Hacking. Our previous iteration was more about understanding the techniques and how it was done. This time around, we've taken a more practical approach and elaborated upon a lot of the techniques along with instructions on how you can execute the same attacks. Hopefully, this practical approach is more enlightening and helpful in the long run.

As usual, we're always eager to have your feedback so do write in to editor@digit.in with your suggestions, remarks and complaints. After all, you are the Ethical Hackers that help Digit improve.
