

safety and security with periodic backups and automated updates, and more.

Risks with Shared Hosting

Since shared hosting is cost-effective, and businesses prefer to opt for this technique, it's important that businesses realise the security threats that come along by implementing this. In addition to very common issues like slow page loading times and customization capabilities, lack of responsiveness from the hosting provider in case of any support requests, there are more serious problems associated with it such as:

- Since all websites reside in the same directory, if there is any compromise on the security of this folder, it will impact all the websites. For example, if a hacker gets access to one of the websites within the shared hosting, it wouldn't take too long for them to access other websites and inject either malicious software or get all the data from the server.
- The hacker can purchase hosting from the provider, become your neighbour in the server family and host his content through which he can gain access to other websites in the server.

Securing the server with multiple CMS installations

In this section, we will take a look at the different techniques and tools that can be used to figure out if multiple CMS installations exist on the same server. So, let's get deeper and understand the steps that can be even used by hackers to crash your website.

1. Reverse IP Lookup

This is the first type of attack every hacker will try to perform on a website to see if it has a shared hosting. If the hacker can backtrack from this, then it becomes very easy to enumerate and find out the list of other websites that are running in the same server. There are several different ways to perform a reverse IP lookup:

a. Free Online Tools

The easiest way to perform reverse IP lookup is by using the YouGet-Signal website. Once you enter the hostname of the website, the website will perform a reverse IP lookup to find other hostnames that are associated with the particular IP. On a shared server, there could be several lists of hostnames that share the same IP as the primary website.
