

Conclusion

It's important for web developers and businesses to develop and deploy websites by considering different vulnerabilities. It's also important for the web administrators to ensure there are no loose ends and loopholes in the website which can potentially open the gates for hackers and attackers to take control of the website. If the website is hosted on a CMS, it's important to perform regular updates and security patches, set up firewall and security for the web application, and have tight access control on the users with validations in place. Make sure you take regular backups of your website, which will help you restore the content in case of emergencies. With trusted CMS providers like WordPress, ensure that you have enabled automatic backups of the website data.
