

code. This helps to add an extra layer of security for the data.

3. Password Strength –

Ensure that you use strong passwords with a combination of alphanumeric characters and special characters. Don't use common terms like “password, welcome@123, India, ...” as passwords as there are easy chances for hackers to guess and

jump into your system. The recommended method is to use password manager software like LastPass, Dashlane, 1Password that helps you generate a random combination of password. As a best practice, make sure to change the password every one or two months to ensure better security of the data. Lastly, remember to log off from the application after every use. Even on a browser window, make sure you log out from the website and clear the cache and cookies data to keep your data safe.

4. Virtual Private Network (VPN) – While on the move, ensure that you connect to VPN when you access critical data or data from the web server. This will ensure encrypted access to the data. Think twice before you connect to a public Wi-Fi network at shopping malls, airports as these are a potential network with prying eyes to hack your data.

5. Be very careful when suspicious opening emails, attachments and links – Since email has become the source of communication, you never know which email is a genuine one and which one is a malicious one. Most of the cyber attacks happening in recent times come

from people clicking unsafe links in emails. An email might look too tempting to click with an irresistible offer that you have never come across, or with some attractive coupon codes to purchase your favourite product. Before opening such emails,
