Everything you need to run Windows programs

Windows users may miss running their favourite Windows programs or games once they move to a PC with Ubuntu. But you can get them back.

Ubuntu is a desktop distribution offered by Linux. Since Windows executables cannot run directly on Ubuntu, we need an interface application to help us achieve this requirement. A few of the popular tools that will assist you to run Windows applications within the Ubuntu desktop are Wine, Winetricks, Play On Linux and Crossover. In the scope of this article, we will focus on the Wine utility.

Wine is the acronym coined for “Wine Is Not an Emulator”. Since Wine interfaces as a compatibility layer for installing, configuring and executing running Windows programs on various POSIX-compliant operating systems, such as macOS, BSD, Ubuntu, Linux, etc., it is not an emulator. It converts Windows API calls into corresponding POSIX calls without degrading the CPU performance and overloading the memory, thus allowing seamless integration of Windows applications onto the Ubuntu environment. Wine can be downloaded from the Ubuntu Software Repositories. Ensure that you select the stable version as it is fully tested and reviewed. The beta version may create problems so please avoid it, if you can. The Wine application database website contains application entries. A search for an application on the website can help to provide the information about the version of Wine and tweaks if any required for that application. It does not require Windows to be installed.
