

For those of you who consider operating Terminal to be difficult and tricky, we don't blame you because the codes may seem difficult to understand, but in reality operating terminal is as easy as learning any Programming Language. You just need to have your basics strong and rest is to be learnt while you implement it.

Why use the terminal?

If we have to answer this question in one line, we would say that Linux is built starting from terminal and then upwards, which means everything in a Linux System is configurable by using Command Line. It is just like a single place from where you can operate all the functions of your operating system. This is essentially the very basis of your Linux Operating system.

Advantages of Using Terminal

As mentioned above Terminal is the single most essential tool in Linux Operating system, now let's look at its advantages to assert that claim:-

- Command Line Codes are standardised through POSIX and Single Unix Specification, so most of the codes you write in your own computer will work in all POSIX compliant machines.
- AS Unix as built from Terminal and then up, almost everything is configurable from the Command Line. Windows used to be just like this but they opted in favour of GUI and now some things can only be done through GUI.
- Because of the flexibility this OS offers, the commands can be piped together, they can be captured and even substituted in some cases.
- As humans are prone to error, even short scripts can be used to change settings in a consistent manner. Even safety scripts can be built by the user rather than relying on which commands are safe to run in different circumstances.
- Unix utilities were designed to do a single task and they do it well, but if you combine them, they can become powerful expressions that can be used in your program.
- It is simply faster than GUI since you just need to write codes and the system will implement them rather than accessing different files from different folders in GUI and then clicking to execute them.
- GUI doesn't cover all of the OS because it was never programmed for some things and only a person with expertise in Command Line can, for example, perform the command `mdf2so`.
