

Linux Commands for Manipulating the System

System Commands are absolutely essential to gain useful knowledge about your Linux System. Numerous powerful system commands are always present at your disposal for this task, some of them are given below to just get you started.

1. `uname`

An elementary Linux command that is used to obtain system information like name, version and other specific details. You can use this command to quickly access the details of your own system.

2. `ps`

`Ps` allows you to view all the processes that are being run by your computer at any point in time. It is an easy way to know analyse system resources and use them according to your need.

3. `kill`

As the name suggests, `kill` command kills processes that are stuck or not executable due to resource constraint.

4. `shutdown`

If you are feeling too lazy or are in a hurry and can't shutdown your program through GUI, just type this command to shut down your computer from the terminal itself.

I/O and Ownership commands in Linux

Linux offers numerous robust commands that deal with manipulating input output streams and file/directory ownership. In this section of the chapter you'll find some elementary commands dealing with the same.

1. `clear`

This command clears the terminal screen for you in one go. As you start to use Terminal more and more, you'll realize the need to clear your terminal screen due to the cluttering created by previous codes and their outputs.

2. `echo`

The `echo` command lets you print a specific text on your terminal screen. You just need to type `echo` and then write the message you want to print
