

This is the fundamental difference. Rebooting on a dual-boot system is quite cumbersome, whereas, for VMs, this doesn't even come into the picture, and you can easily run your secondary OS in a VM.

VM Programs which are widely used

Although this is not a mandatory option, you should activate virtualisation on your PC before using VM software.

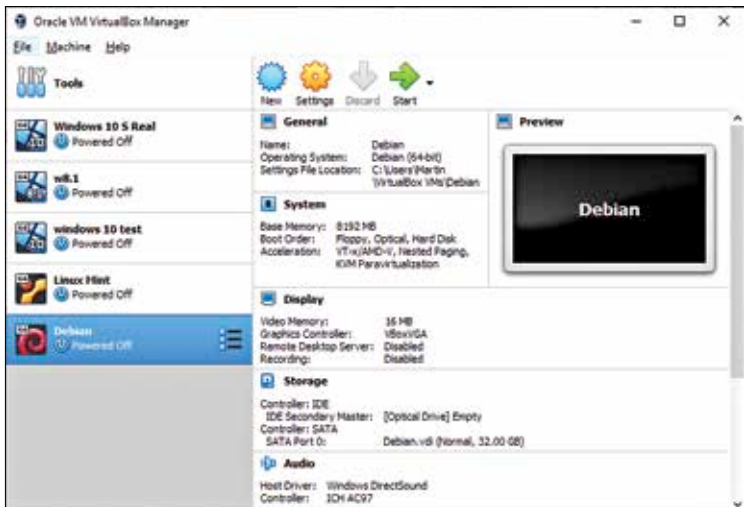

Here's how you activate virtualisation:

1. Access system BIOS (by pressing delete or F2 after rebooting the PC) (Remember, BIOS is navigated through arrow keys)
2. Go the "Advanced" screen, and find one of these:
 - a. AMD-v
 - b. VT-x
 - c. Virtualisation
3. Enable the setting you found in Step.2, and you're good to go!

Now, here are some of the popular VM programs:

- **VirtualBox by Oracle**

Released more than a decade ago, this free to use program supports numerous guest OSs. It is compatible with most Linux Distributions,

VirtualBox running Debian
