

Other

Other can be considered as one super group which contains all the users who have the access to the system. In other words, a user in a singular identity, a group is a collection of similar user and other consists of all the users on the system.

File Permissions in Ubuntu

Before we review the Access permission sets for each directory, let us underline some basic rules and assumptions of file permissions.

- Each group of permissions includes three permissions and is called a permission set.
- Each permission set consists of read, write and execute permissions.
- Each file and directory consists of three permission sets for three types of owners.
- The first set of permissions represent the user permissions, the second set of permissions represent the group permissions and the third set represent the permission for others.
- The read, write and execute permissions are represented by r, w, x respectively.
- The presence of any of these symbols, r, w, x means that the particular permission is granted.
- A hyphen instead of any of the three characters means that the particular permission for the particular owner is denied.

ACCESS PERMISSIONS FOR FILES	ACCESS PERMISSIONS FOR DIRECTORIES
Read- The user can read or copy the contents of the file	Read- The user can list all the files and copy them from the directory
Write- The user Can modify and delete the contents of the file	Write- The user can add or delete files in the directory but this permission also needs execute permission
Execute- The user can run the file if it is executable	Execute- The user can enter the directory

Understanding File Permissions and File Ownership

Now that you have got the basic idea, let us get into the details of the same and see the real action.
