

File permissions symbols

means the group can't execute this particular. Like before you can determine the identity of this particular group by using `ls-l`

- The file has only the read permission for other user which means that other users only have access to the system but can't modify or execute it. You don't need to determine who the others are here, other includes all the users that have access to the system.

Now if you type the command `ls-l` again, you'll be able to determine the file permissions and ownership together.

Note that root users have superpowers, they normally have read, write and execute permissions for all files in the particular even when it doesn't show in the file permissions. We will talk about this a little later.

2. A single user can be a member of numerous groups but only the primary group of the user is the principal owner group of the group created by the user. The primary group of a user can be found using the command `id-gn<username>` and if you want to know your own primary group, leave the username blank.

Now that you have got the idea of file and directory permissions, let us look at ways that you can change these permissions whenever the need arises.

Changing File and Directory Permissions in Ubuntu

You can change the permissions of your file or directory from terminal as well as through GUI. We will look into both of these in details in the following section.
