

brief, you will find the troubleshooting of most common problems associated with the Linux server.

1. Check for the configuration

Always be sure that network interfaces over server are enabled like eth0. If you want to see all the active configuration interfaces on the server then you can use the following command-

- `ip addr`

The output which you will receive from this command will distinctively show the actual status of interfaces as 'state UP' and 'state DOWN'. If you want to turn on the disable interface over the server then you can use-

- `sudo ifup <interface name>`

Once you have enabled all the interfaces then and you can easily use the ping command. If the problem still remains the same then you have to check the assigned IP address. Also, make sure that they resemble the related network server of the cloud control panel. If you want to restart the interface which is creating troubles then use the following command-

- `sudo ifdown <interface name>`
- `sudo ifup <interface name>`

2. Monitor the files of network configuration-

One major advantage of Linux is that most of the network settings are stored in individual files. At the time of boot or using ifup command, it also reads the files. If you are trying to make the changes in configuration files then it is essential to open the suitable file in the editor. In Ubuntu, it can be done with the help of command-

- `sudo nano /etc/network/interfaces`

3. You have to check the DNS records of server

If the ping command which we have used along with the IP address was active but the regular connection remains to fail then you have to ping the domain name. Let's learn this by an example.

If you use the ping command for the Upcloud domain and domain does not reply back then you can use the following command as-

- `Ping Upcloud.com`
