

- Grab the file from Ubuntu's official site. There will be LTS and non-LTS versions listed. Go with LTS (long term support) if you want stability and regular updates. The latest long term support version available on the website is 18.04.2.
- Once you have the ISO file on your system, you need to burn the image to a USB stick and make it bootable. Windows users generally prefer Rufus while balenaEtcher is the go to tool for most of macOS and Linux users. Ubuntu users have a ready-made tool by the name of 'Startup Disk Creator' pre-installed on their systems which is more than enough for our current job. The whole process can be completed in a few simple steps and the instructions for the respective applications are available on their official sites. Just beware the you'll lose all the data on the disk you're using as your bootable drive.
- Now you need to change the boot order so that your system recognises the OS on your USB. Windows, macOS and Linux, each of them have separate ways to deal with this. Linux users should be more careful as the process requires them to change the grub file and it's best practice to make a backup copy of the grub file before editing it.
- After completing all of the above steps, just restart your system. The boot prompt will take you through several different options to set up the OS, choosing the language, time zone, username and password and several other details.
- During the installation process, you will be required to select the installation type, a normal installation or a MAAS (Metal as a Service). The MAAS have cloud provisioning and if you don't necessarily require that, it's better to go with the normal one.
- The next step will be configuring the network settings. First select the network adapter and accept automatic assignment of the IP address if you're operating with a DHCP environment or you can choose to manually configure the IP address.
- Moving on to proxy settings. If you have a proxy server address, go ahead and enter that else skip the step.
- Network mirror: Leave it to default the default setting.
- Hard disk setup: You can either use your whole hard-disk or if you've made partitions, you can select them at this stage. Remember that your partitions should be large enough.
- File system summary. Time to recheck the entire thing. If you notice any mistakes simply go back and make the necessary changes.
