

- Set up your login credentials.
- After the installation is complete, we need to do a bit of cleaning and upgrade.

- `$ sudo apt-get update/`

This following command will display a list of packages that can be upgraded.

- `$ sudo apt list --upgradable`
- `$ sudo apt upgrade`

Wait for a few minutes for the download and upgrade to finish. Following this upgrade it's better to remove unused files and system folders which sometimes much space.

- `$ sudo apt autoremove`
- `$ sudo apt clean`

Creating a new user

In the terminal and type in :

- `$ sudo passwd root`

You will be prompted to enter the user password which you had set during the installation process. After then you'll have to enter a new password. After completing this step enter:

- `$ su ~`

Enter the newly created password and upon the successful execution of this command you'll have yourself root privileges which can then be used to manage root privileges for other files and operations.

- Executing commands with root privileges can have unwarranted and sometimes disastrous results for your system. Therefore it is advisable to create a new user to manage server operation instead of root. So, let's see how to go about creating a new user which will be used to carry out administrative tasks.

- `$ sudo adduser new_user` (new_user can be any name of your choosing)

- As of now the new_user does not have administrative privileges. We need to add this user to an esoteric group called the 'sudo' group. Type the following command to grant it those permissions:

- `$ sudo usermod -a -G sudo ubuntu_user`
