

1. **Zircon:** The first layer of Fuchsia is its basis of foundation, called Zircon. This one will be where the OS will draw most of its powers from. Simply put, this will be the heart of Fuchsia, with an extensive array of micro-kernel, libraries, smart space for users, and drivers.

This layer will be responsible for all booting activities of a device, besides allowing the user to communicate with the hardware using the smart user space that it will contain.

2. **Garnet:** This layer is the ‘manager’ of Zircon. This second layer of Fuchsia will be handling the drivers present in the previous tier, making it accountable for all operations.

Garnet, in turn, has a flexible design and includes a few more layers of its own. While Escher will be taking care of the graphics, Amber will be present to update the device. It will be primarily used to incorporate updates from Google.

This is to be seamless, giving the devices a lot of scope for improvement. Xi Core, on the other hand, is the code editor that will enhance the performance overall.

3. **Peridot:** Peridot, the third layer, is to take care of Fuchsia’s modularity. To do so, it has been given layers of its own, very much like Garnet. This will truly make it modular in approach.

Agent, the first component of Peridot, is the underdog that will provide information to the other parts. Module is the component that will
