

been using to build their apps, Flutter has a core library stuffed with widgets and graphics. This further makes the work of the programmers easier, as they do not have to worry about designing these from scratch.

4. **Building efficient prototypes:** Building prototypes is one of the most important aspects of designing anything related to technology. With Flutter, that becomes exponentially easy. With its reactive design, programmers can easily build a prototype and track all the changes that they want to further make on their apps.
5. **Easy to make changes in the design:** Flutter has shown groundbreaking results in case of easy designing techniques. It allows the developers to debug their codes without additional hassles, while also allowing them to track further changes on their apps.
6. **Custom-made applications without restrictions:** Prior to the release of Fuchsia, applications had to be designed on restricted OEMs, that made it even more difficult for programmers to design the applications as per their choice. However, with the inception of Flutter, all of that has been taken care of. Developers now get the option to incorporate their unique designs in their apps, without any unnecessary condiments.
7. **Flutter is an open source software:** A big advantage that is predicted to take the software a few notches higher, is the fact that it is open source. This means that users can download the software from the Internet, for free. This makes the deal even more lucrative, as programmers are not required to spend a penny on platforms to design their applications. It, in fact, gives them a hundred percent profit.

Getting started
