

Writing a sample app to test the installation

Once you are done with the installation process, it is time for you to code. It is recommended that the user first write a sample app before proceeding with the real work. Installations can often be cumbersome, irrespective of how good the software is. Hence, to prevent any untoward incidents, it is always better to check all features thoroughly before using. Once the sample app passes your test, you can proceed to use Flutter to design your own applications.

Introduction to Dart

Dart is the programming language that powers Flutter. It was developed by Google as a general-purpose and language for developers. It was to serve as an efficient alternative to build mobile applications, servers, and web pages.

Dart has been influenced largely by Java, the language that is used to write the most complicated codes. Hence, Dart is accepted worldwide due to its resemblance to the most-used language. Needless to say, much like Java, Dart follows the principles of OOP, or Object-Oriented programming. Hence, it supports, abstraction, encapsulation, data hiding, and other such features.
