

AppBar and GestureDetector widgets, on the other hand, allow the leading and the actions of the title widget and detect gestures of the user.

It's All in the Keys

Keys are used, in Flutter, to control the matching widget frameworks during a widget rebuild. Through default, this framework matches widgets in the present and the previous built based on their runtime Type and the order in which they appear. The two matching widgets are required to have the same runtime Type and the same keys.

Global keys, on the other hand, are used for uniquely identifying child widgets. The main difference between global and local keys is that the global keys have to be globally unique throughout the widget hierarchy. Local keys need to be unique only among siblings. A global key can also be used for retrieving the state primarily associated with a widget.

Build it With a Widget

A layout in Flutter is created by adding widgets to build many more complex widgets. This takes us back to the point where we had originally started. Revising quickly, UIs in Flutter is specifically meant to be built through widgets.

The process of laying out a single widget and multiple ones in Flutter involves just a few simple steps. As already mentioned, Flutter contains a large library of layout widgets. The Widget Catalogue gives us a list of all of these. Widgets generally fall into two broad categories. These are the standard widgets which are contained in the widgets library and specialised widgets which can be found in the Material library. However, the material library can be used by a material app only.

Animate It

Flutter also provides animation support, which makes it possible for one to implement a wide array of animation types into one's application. Several widgets, especially the Material Widgets, come with a range of standard motion effects which are defined in their design spectrum. Flutter also allows customising these effects to suit one's preferences.

Take It a Step Ahead

Advance UI comprises of Silvers and Gestures. Silver comprises the scroll roll area. It is used to achieve custom scrolling effects. A gesture comprises
