

Finding Out the Right JSON Serialization

Every app at one point must connect to a web server and store some structured data. This means that the app must need JSON sooner or later.

One can use manual JSON serialisation or automated JSON serialisation using code generation on Flutter. Manual decoding works well with smaller projects. However, larger projects succeed only with the use of code generation. This implies having an external library for the purpose of generation of encoding boilerplate for one's application. Flutter does not contain GSON/Jackson/Moshi equivalent.

Firestore

Firestore has been defined as a 'Backend-as-a-Service (BaaS) app development platform that provides hosted backend services such as a real-time database, cloud storage, authentication, crash reporting, machine learning, remote configuration, and hosting for one's static files.' Flutter finds support in Firestore.

Accessibility and Internationalisation

What is accessibility?

The most important feature of an app must be its capability to be used by many. Accessibility, therefore, follows its simple meaning: an application being accessible to a vast number of users, which also include people living with disabilities.

Flutter provides three components for accessibility support: large fonts which render text widget with font sizes as desired by the user; screen readers for communicating spoken feedback about the UI contents and ample contrast for rendering widgets with such colors.

What is Internationalisation?

If one's app is to be potentially used by users who speak different languages, one must consider internationalising it. This implies that the application is written in a manner where it is possible to localise features like texts and layouts for each language and the locale that the app supports. Flutter comes with widgets and classes which help with the process. Flutter libraries are themselves internationalised. By default, Flutter provides US English localisation. For supporting other languages, an application should specify additional MaterialApp properties. They should also include a set of a package called flutter_localizations. This package supports
