

Flutter or the perks that it provides to users, designers and developers; but also destroys the goodwill and credibility of Google.

Debugging is the procedure which is employed in finding out any inherent defects or problems that might be present in a computer program since its generation, and might cause operational malfunction later. Flutter uses an array of debugging techniques to search for any such programming faults and mend them. The applications developed through the Flutter framework are thus resolved of any such problems. The debugging procedures in play that make Flutter, a suave and smart framework in operation are -

- **Dev tools:** Dev tools are touted as the most commonly-used tool employed for debugging and profiling procedures for applications. This is because it boasts an array of features, with the most noteworthy being its accessibility and functionality over a wide variety of platforms. Dev tools itself run in a browser and can be put to use as a source-level debugger, a widget inspector that displays all the widget information and tends to the malfunctioning widget in concern, a memory profiler, a timeline profiler which can trace timelines as well

Be an absolute wizard at app development with Flutter

as import and export these information, and also as a logging viewer. Though Debug mode or Profile mode allows for easy connection and debugging action of Dev tools in a separate browser with the original application; the Release mode does not work quite as well with Dev tools.

- **Setting up of breakpoints:** Installing breakpoints directly in the integrated developed environment or the editor; like IntelliJ/Android Studio,
