

asserted statement encountered during execution. Only if the result is false the analysis isn't done. This helps the developers to enable or disable invariant checking methods during the process so that the associated performance cost is only paid during tracking and debugging sessions and cut down any additional costs.

- **Animation Debugging:** The Flutter inspector is loaded with a Slow Animation button which allows any animation to slow down and thereby the debugging is done in the most effective way.
- **Measuring the app startup time:** Utilising the inbuilt Flutter commands to measure the exact time s that the application requires to start and run each process successfully. Putting a trace on the startup time enables the debugging tools to get active if there is any deviation from the normal.
- **Dart code tracing:** While running the application in profile mode, Flutter can offer performance traces to be done which can be viewed either by Dev Tools timeline view impulse or can't be viewed because of the trace was done programmatically. This enables seamless debugging.
- **Performance Overlay feature:** The unique feature of Performance Overlay enables the Flutter app to view the entire performance data in a graphical fashion, aiding in a better understanding of the same.
- **Presence of Debug flags:** The Dev Tools suite provides the best functionality in debugging performance and the direct usage of Debug flags can be avoided, which, on the other hand, provoke a direct usage if the Dev Tools suite doesn't come into play.

The aesthetic of Flutter apps is often commended
