

- **Presence of common problems:** The number of files that can be simultaneously handled by a macOS is limited. Hence often a problem arises which displays Too Many Files Open on the same OS. This problem can be taken care of by deploying a greater number of file handlers like Cirrus.

Debugging Flutter applications in a programmatically correct method

- **Logging:** Enabling logging view mode in the DevTools setup or on the console, one can view debugging actions. This can be done after they assert the correct logging statements if they choose to ignore the DevTools functionality setup.
- **Displaying Network Traffic:** The network traffic to a particular application can be tracked or displayed by using a preview version of the application which allows users to monitor it by utilising logging view.
- **Enabling Breakpoints:** Installation of Breakpoints is made possible using the in-built debugging of the Flutter set up or the DevTools debugging suite or using the correct programming language.
- **Enabling Debug flags:** Since the architecture of Flutter is such that it offers multiple layers of widget, painting, and renderings; debug flags can be installed using proper programming language because each layer of Flutter are capable of dumping their present state in the console. Hence debugging becomes an easy task as one has to effectively set up the ideal command statement in order to call the corresponding Debug Flag. This enables debugging action using debug flags in widget trees, application layers as well as rendering trees.
