

A dump of the application layer tree, rendering tree, widget tree, semantics tree (the entire details of the data presented to the system accessibility APIs) can be obtained and debug flagging commands can be established accordingly. The debug files can also be installed to find out and correct any vision problems that may occur in the layout. Scheduling enables debugging action to be taken effortlessly because of the application's run time can be measured the frame to frame with respect to the normal beginning and ending time schedules.

- **Debugging performance issues:** Debug flags can be set up at various breakpoints of an application running procedure using the ideal command language to call forth the ideal functions. These help in analyzing the performance issues of the application at various points and install the particular flags would enable debugging options automatically. DevTools setup, as well as the inbuilt debugging tools, would perform these checks without command prompts.
- **Tracing Dart code performance and performance overlay:** Since Dart analysers act automatically detecting malware, tracing Dart code information using ideal time-bound traces facilitates to study the application performance.

To view the overall performance through visual data representation in the form of graphs, programmatically manipulating the performance overlay widget is the ideal solution.

- **Widget alignment grid options:** Programming language using the ideal command prompts help in overlaying a standardized Material Design Baseline Grid over the application grid to verify the correct alignments.
