

Employing an OEM debugger

OEM stands for original equipment manufacturers that are the personnel who design and manufacture the particular device. Here the equipment in concern is Flutter.

Flutter uses original inbuilt Dart code debugger from its own IDE or editor which facilitates debugging solutions if the application is entirely developed using the Flutter framework and has no contribution inbuilt on other platform-specific software. This can be achieved in a three-pronged fashion.

- **Debugging Dart code:** Standard Dart debugging may be obtained using the inbuilt IDE of Flutter and its other associated Plugins which should be necessarily installed and configured. But the same can be achieved using Android Studio application which offers the necessary configurations to be done for customised Dart debugging. Installing breakpoints using the OEM debugger is a major resolver of tracking and mending issues.
- **Flutter Inspector:** Flutter Plugins offer the additional feature of widget inspector which helps in visualising and understanding the entire widget tree of the application by pointing out layout issues and understanding existing layouts.
