

Recipes are provided through tap, drag and enter text and even Find widgets category.

- **Integration tests:** Integration tests verify the synergy of the widgets and services, as to whether they can perform in an optimised fashion

simultaneously. They test almost the entirety of the application or the entire application in itself. The integration tests verify the overall performance of the application.

The app which is being tested should be isolated from the test driver code to avoid the variance of results from the one that is to be obtained. An integration test offers seamless functionality over the real device or an emulator or simulator, which can vary from iOS to Android to any other OS. Recipes can be provided through Handle scrolling or Performance profiling.

- **Continuous Integration Services:** Continuous integration services offer the accessibility of performing the test while introducing new code changes. This helps in predicting in real-time whether the code changes work as expected in the future and do not introduce bugs. Recipes can be understood from continuous fast lane services on Flutter and understanding Flutter apps on Travis and Cirrus.

Practices that boost the Performance to its peak

Generally, by default, Flutter applications are hyper performant. Therefore the micro-management that involves the optimisation of complicated tools that support profiling does not pose any problems in Flutter. Instead, the
