

FlutterInspector

Turn of the logging and debugging options

Ensure that you deactivate logging and disable debugging before you start building your application for the final release. You can also deactivate logging by removing the calls to log methods in the source files of the application, while you can shut off debugging by simply removing the Android debuggable attribute from the <application> tag in your manifest file. One more way to do it is by setting the android:debuggable attribute to false in manifest file. Additionally, remove any and all log files or static test files ever created in the project.

Important: You need to ensure that you disable debugging for your app, if using WebView to display paid for content, or if using JavaScript interfaces because debugging allows users to inject scripts and extract content using Chrome DevTools. In order to disable debugging, you can use the `WebView.setWebContentsDebuggingEnabled()` method.

Cleaning up the directories

You should make it a point to clean up your project directories and ensure that it conforms to the standards given under Android Projects because leaving any unattended or stray files can prevent your application from getting compiled and result in misbehavior of your application.
