

```

• Widget build(BuildContext context) {
•   return new MaterialApp(
•     title: ' FT Calculator Demo',
•     theme: new ThemeData(
•       primarySwatch: Colors.blue,
•     ),
•     home: new FTCalculatorPage(title: 'FT Calculator'),
•   );
• }
• }

```

In the preceding code snippet, MyApp class extends the StatelessWidget class as everything in a Flutter app even the app itself is treated as a widget. You already know that widgets can be either stateless or stateful. Stateless widgets are static and cannot change their state over time. This class has a build() function, which returns a material app. The material app has a few properties, such as home property, which takes an object of type FTCalculatorPage, which intern takes the title as a parameter. Another one is the theme property, which allows playing with the theme of the app and here, we have set the app color as blue.

5. Create a class with the name FTCalculatorPage just below that by using the following code snippet:

```

• class FTCalculatorPage extends StatefulWidget {
•   FTCalculatorPage({Key key, this.title}) : super(key:
key);
•   final String title;
•   @override
•   _FTCalculatorPageState createState() => new _FTCalcula-
torPageState();
• }
• You must have noticed that the FTCalculatorPage class
extends the StatefulWidget class. Stateful widgets can
change their states in response to the actions performed
by the users.

```

6. Now, just below the FTCalculatorPage class, add another class with the name _FTCalculatorPageState by using the following code snippet:

```

• class _FTCalculatorPageState extends

```
