

```

    child: new Text(buttonText,
      style: TextStyle(
        fontSize: 20.0,
        fontWeight: FontWeight.bold
      ),
    ),
    onPressed: () => {},
  ),
);
}

```

The preceding `ftCalcButton` function takes the button text as its parameter. The button text parameter stores the text to be displayed on the button. The `ftCalcButton` function returns an `Expanded` object that wraps `OutlineButton` as the child widgets. In the function, a custom button widget is defined where the font size of the button text is 20 and the font-weight is bold. You can also change the color of the buttons and the button texts by using the `color` and the `textColor` properties.

You have added a property called `onPressed` to all the buttons to make them function. The `onPressed` property should be associated with a function, which should contain the code to define the functionality of each button. At present, you can tap on the buttons but they will perform nothing as we have specified `() => {}`.

9. Replace the `_FTCalculatorPageState` class by using the following code snippet:

```

class _FTCalculatorPageState extends
State<CalculatorPage> {
  @override
  Widget build(BuildContext context) {
    return new Scaffold(
      appBar: new AppBar(
        title: new Text(widget.title),
      ),
      body: new Container(
        child: new Column(
          children: <Widget>[
            new Container(
              alignment: Alignment.centerRight,

```
