

some interactivity to the buttons to make the calculator working. To add interactivity, you need to perform the following steps:

1. Replace `onPressed(): => {}` with `onPressed(): => buttonPressed(buttonText)` inside the `ftCalcButton` function.
2. This specifies whenever you tap any button on the app, the `buttonPressed` function will be executed.
3. Add the following expressions at the next line below class `_FTCalculatorPageState` extends `State<FTCalculatorPage>` {

```
• String output = "0";
• String _output = "0";
• double num1 = 0.0;
• double num2 = 0.0;
• String operand = "";
```

The `_output` variable is used to store the updated output that is not ready to be displayed on the view. The output variable is used to store the final result that needs to be displayed on the screen. The two variables, `num1` and `num2`, store the input numbers, and the operand variable stores the selected operand. Based on the value stored in the operand variable, the required operations will be carried out.

4. Then, define the `buttonPressed` function that takes the button text as its argument:

```
• buttonPressed(String buttonText){
•
•     if(buttonText == "CLEAR"){
•
•         _output = "0";
•         num1 = 0.0;
•         num2 = 0.0;
•         operand = "";
•
•     } else if (buttonText == "+" || buttonText == "-" ||
buttonText == "/" || buttonText == "X"){
•
•         num1 = double.parse(output);
```
