

Step 3:**Implementing the button row**

The next step is to implement the button row correctly, with proper margins and alignment.

- The button row has 3 columns that use a similar layout—an icon over a row of text. The columns in the row are spaced evenly, with icons and text painted in primary colors.
- The code for building each column is more or less identical. So, create a private helper method - `buildButtonColumn()`. It takes a colour, an Icon and Text, and in return, gives a column with its widgets painted in the required color.

Button section of Flutter

- The icon is added directly to the column. There is a top-only margin, separating the icon from the text, which is inside a Container.
- To build the row containing these columns, call the function and pass the color, Icon, and text specific to the column.
- The columns should be aligned along the main axis using `MainAxisAlignment.spaceEvenly` to arrange the free space evenly.
- Add the required code just below the `titleSection` declaration inside the `build()` method.
- Add the button section to the body.

Step 4:**Implementing the text section**

Now, you need to successfully implement the text section by following the simple steps as given below.
